(d) The recursive procedure `OutputInOrder()` outputs the data stored in the binary tree in ascending numerical order.

The procedure takes a `Node` object as a parameter and then:

- checks if the left node is null. If there is a left node, the function calls itself with the left node
- outputs the data of the current node
- checks if the right node is null. If there is a right node, the function calls itself with the right node.

Write program code for `OutputInOrder()`

Save your program. Copy and paste the program code into part **3(d)** in the evidence document.

[5]

(e) **(i)** Write program code to extend the main program to:

- create a new object of type `Tree` with the node containing the data 10 as the first node
- insert the nodes with the values 20, 5, 15 and 7 into the tree in the order given
- call `OutputInOrder()` with the tree's root node as a parameter.

Save your program. Copy and paste the program code into part **3(e)(i)** in the evidence document.

[3]

(ii) Test your program.

Take a screenshot of the output(s).

Save your program. Copy and paste the screenshot into part **3(e)(ii)** in the evidence document.
