

These boundaries mark the upper limits of the addresses available to each application (addresses start at 0 and end at Z); the boundaries ($A + 1$, $B + 1$, $C + 1$) are often referred to as a FENCE

A FENCE defines the boundary between the operating system and the applications; it is not possible for an application to access a memory location which is lower than the FENCE address

Address	Memory
0 ↓ A	operating system
Boundary location is at address ($A+1$)	
$A + 1$ ↓ B	memory allocated to application 1
Boundary location is at address ($B+1$)	
$B + 1$ ↓ C	memory allocated to application 2
Boundary location is at address ($C+1$)	
$C + 1$ ↓ Z	memory allocated to application 3
Upper limit to address value (Z)
