

- 4 (a) State what is meant by diffraction of a wave.

.....

.....

..... [2]

- (b) A beam of vertically polarised light of wavelength 540 nm is incident normally on a diffraction grating, as shown in Fig. 4.1.

Fig. 4.1 (not to scale)

The diffraction grating has a line spacing of $5.0 \times 10^{-6}\text{ m}$.

The light transmitted by the diffraction grating illuminates a circular screen. The diffraction grating is at the centre X of the circle.

The central bright fringe is formed at point O on the screen and has intensity I_0 .

P is a point on the screen where the line XP is at a variable angle θ to the line XO. The intensity I of light on the screen at P varies with θ .

- (i) Show that the angle θ at which the first-order bright fringe is formed is 6.2° .
